

Erica Synths Black Octasource

Stereo Patch

Audio
Control Voltage
Trigger / Gate

(a)

a - Here is a simple voice, made with an oscillator and filter. It's multiplied to two VCAs, to create a stereo signal. Then the first and fifth shifted sinewaves of the Octasource are used to open and close those VCAs, to create stereo movement. When you add a manually controlled attack-hold-decay envelope to the Octasource's frequency cv input, you can create an interesting rotary-like effect.

TECH TALK

(b)

b - By using outputs with different phases you can change the movement in the stereo field. In this drone patch both the outputs of the Octasource are multiplied to the filter. It's worth it to experiment with different waveforms in simple setups like this.

Wave Morphing / Voice Modulation

Audio
Control Voltage
Trigger / Gate

(a)

a - Another great way to use the shifted outputs, is to create custom wave-morphing. In this patch the main and sub output from one oscillator, and two other waveforms from a second oscillator, are sent to four VCAs with a summing output, so we can listen to the mix out. Then you can send four phase shifted outputs from the Octasource to open and close those VCAs, to create morphing waveshapes.

MONOTRAIL TECH TALK

(b)

b - This patch has a simple drone voice, made with a wavetable oscillator, a delay, and a filter. You can use different shifted outputs of the Octasource to modulate multiple parameters in this simple voice. For example, the oscillator's waveshape, the delay time, the filter cutoff, and the filter resonance. Because all the waveforms from the Octasource are related, it's easy to create rich synchronized movement in patches.

Patch Modulation

MONOTRAIL TECH TALK

(a)

a - Synchronized modulation also works great in large complex patches with multiple tonal and percussive voices. Besides the drone voice from the last patch, there's a second voice with two filters and an effect module. Two other outputs of the Octasource are used to modulate the filter and effect module. There's also a sample player, playing some single drum hits through a VCA, as well as a drum voice. Both the sample player and the drum voice are clocked with the help of a clock divider. Finally, the remaining outputs of the Octasource are used to modulate a parameter on the drum voice and the sample player, as well as the VCA.

Depending on which outputs you use, you can choose where in time certain movement occurs. The Octasource is the only modulation source in this patch, so messing around with different waveshapes and frequencies will have a huge impact on the sound.

In this patch the Octasource is synced to a clock division. But for more organic movement you can also have it run free.

Patch Modulation 2

MONOTRAIL TECH TALK

- Audio
- Control Voltage
- Trigger / Gate

(a)

a - You can create an interesting patch if you set the Octasource base frequency close to zero, so it doesn't change value on its own. Here we use that trick on the larger patch we just created. The only difference is that the clock divider also gates an attack-hold-release envelope, which is sent to the Octasource's frequency input.

Now, every time the clock division gates the envelope, the Octasource will speed up, starting to modulate. But when the envelope dies out, the modulation will come close to a halt, creating a very organic transition between motion and a hold value.

Clocked Modulation / Looping Sequences

Audio
Control Voltage
Trigger / Gate

(a)

a - Here's a simple kick and a steady baseline made with a wavetable oscillator, a delay, filter, and VCA. A steady clock and divider are used to gate the kick and an envelope, that in turn opens the VCA and filter of the baseline. Then, you can use the Octasource to modulate things like the waveshape, delay time, and filter cutoff. If you sync the Octasource to a division from the clock, you get a voice with complex but related rhythmic modulation. By changing the waveshape you can search for the movement you like. This can sound great in both 'single' and 'multi' mode. And by applying a subtle amount of modulation to the waveshape input of the Octasource you can also automate that movement.

(b)

b - It's also interesting to use the Octasource to create looping melodies. Just feed a few of the outputs to a mixer, and then to a quantizer, to sequence a voice. Playing with the different modes and simultaneously either having the Octasource running free, or tempo synced to a clock, can create a lot of different related signals. Then just use the mixer to mix and morph between different sequences.
